Web Application Report

This report includes important security information about your Web Application.

Security Report

This report was created by IBM Rational AppScan 8.5.0.1
1/9/2013 1:49:15 PM

Report Information

Web Application Report

Scan Name: ncias-d704-v-example_010813

Scanned Host(s)

Host	Operating System	Web Server	Application Server
ncias-d704-v.nci.nih.gov:29080		Apache	Apache AXIS

Content

This report contains the following sections:

- Executive Summary
- Detailed Security Issues
- Remediation Tasks
- Application Data
- Application URLs
- Advisories & Fix Recommendations

Executive Summary
Test Policy

- Default

Security Risks

Following are the security risks that appeared most often in the application. To explore which issues included these risks, please refer to the 'Detailed Security Issues' section in this report.

- It is possible to retrieve the source code of server-side scripts, which may expose the application logic and other sensitive information such as usernames and passwords
- It is possible to view, modify or delete database entries and tables
- It is possible to gather sensitive debugging information
- It is possible to steal or manipulate customer session and cookies, which might be used to impersonate a legitimate user, allowing the hacker to view or alter user records, and to perform transactions as that user
- It may be possible to steal user login information such as usernames and passwords that are sent unencrypted

Vulnerable URLs

22% of the URLs had test results that included security issues.

■ Vulnerable URLs (22%)
☐ Not vulnerable URLs (78%)

Scanned URLs

2221 URLs were scanned by AppScan.

Security Issue Possible Causes

Following are the most common causes for the security issues found in the application. The causes below are those that repeated in the maximal number of issues. To explore which issues included these causes, please refer to the 'Detailed Security Issues' section in this report.

- Debugging information was left by the programmer in web pages
- Latest patches or hotfixes for 3rd. party products were not installed
- Temporary files were left in production environment

- Sanitation of hazardous characters was not performed correctly on user input
- No validation was done in order to make sure that user input matches the data type expected
URLs with the Most Security Issues (number issues)

- http://ncias-d704-v.nci.nih.gov:29080/example/GetHTML (18)
- http://ncias-d704-v.nci.nih.gov:29080/example/Result.action (7)
- http://ncias-d704-v.nci.nih.gov:29080/example/docs/index.html (2)
- http://ncias-d704-v.nci.nih.gov:29080/example/docs/system/index.html (2)
- http://ncias-d704-v.nci.nih.gov:29080/example/ (1)

Security Issues per Host

Hosts	High	Medium	Low	Informational	Total
http://ncias-d704-v.nci.nih.gov:29080/	2	1	308	8	319
Total	**2**	**1**	**308**	**8**	**319**

Security Issue Distribution per Threat Class

The following is a list of the security issues, distributed by Threat Class.

Security Issue Cause Distribution

99% Application-related Security Issues (318 out of a total of 319 issues).
Application-related Security Issues can usually be fixed by application developers, as they result from defects in the application code.
1% Infrastructure and Platform Security Issues (1 out of a total 319 issues).
Infrastructure and Platform Security Issues can usually be fixed by system and network administrators as these security issues result from misconfiguration of, or defects in 3rd party products.

Detailed Security Issues

Vulnerable URL: http://ncias-d704-v.nci.nih.gov:29080/example/

Total of 1 security issues in this URL

[1 of 1] Insecure HTTP Methods Enabled

Severity:	Medium
Test Type:	Infrastructure
Vulnerable URL:	http://ncias-d704-v.nci.nih.gov:29080/example/
CVE ID(s):	N/A
CWE ID(s):	N/A
Remediation Tasks:	Disable WebDAV, or disallow unneeded HTTP methods

Variant 1 of 1 [ID=6452]

The following changes were applied to the original request:
• Set method to 'PTIONS'

Request/Response:

```
OPTIONS /example/ HTTP/1.1
Cookie: JSESSIONID=023A3E78DD553AD51457C10BA07B44F3
Content-Length: 0
Host: ncias-d704-v.nci.nih.gov:29080
User-Agent: Mozilla/5.0 (Windows NT 5.2; rv:10.0.11) Gecko/20100101 Firefox/10.0.11
Accept: text/html,application/xhtml+xml,application/xml;q=0.9,*/*;q=0.8
Accept-Language: en-us,en;q=0.5
Connection: Keep-Alive

HTTP/1.1 200 OK
Content-Length: 0
Server: Apache-Coyote/1.1
X-Powered-By: Servlet 2.5; JBoss-5.0/JBossWeb-2.1
Allow: GET, HEAD, POST, PUT, DELETE, TRACE, OPTIONS
Date: Tue, 08 Jan 2013 16:06:49 GMT
```

Validation In Response:

• Allow: GET, HEAD, POST, PUT, **DELETE**, TRACE, OPTIONS

Reasoning:

The Allow header revealed that hazardous HTTP Options are allowed, indicating that WebDAV is enabled on the server.

CWE ID:

N/A

Vulnerable URL: http://ncias-d704-v.nci.nih.gov:29080/example/docs/index.html

Total of 1 security issues in this URL

[1 of 1] Unencrypted Login Request

Severity:	High
Test Type:	Application
Vulnerable URL:	http://ncias-d704-v.nci.nih.gov:29080/example/docs/index.html
CVE ID(s):	N/A
CWE ID(s):	523
Remediation Tasks:	Always use SSL and POST (body) parameters when sending sensitive information.

Variant 1 of 4 [ID=115671]

The following may require user attention:

```

Advisories & Fix Recommendations

Google Search Appliances UTF-7 Cross-Site Scripting

Infrastructure

WASC Threat Classification

Cross-site Scripting

http://projects.webappsec.org/Cross-Site+Scripting

CVE ID(s)

CVE-2006-6223

CWE ID(s)

N/A

Security Risks

It is possible to steal or manipulate customer session and cookies, which might be used to impersonate a legitimate user, allowing the hacker to view or alter user records, and to perform transactions as that user

Possible Causes

A vulnerable third party software, which does not have a known patch, is installed on the Web site

Technical Description

Google Search Appliance and Google Mini do not properly sanitize input passed to the "q" parameter in UTF-7 before it is returned to the user.
This can be exploited to mount Cross-Site Scripting attacks through the site.

General Fix Recommendations

We are currently unaware of any fix available for this issue. However, we highly recommend contacting the vendor of this product to see if a patch or fix has recently been made available. You may also want to check one of the following security sites for any new findings regarding this issue:

Microsoft Windows MHTML Cross-Site Scripting

Application

WASC Threat Classification

Cross-site Scripting

http://projects.webappsec.org/Cross-Site+Scripting

CVE ID(s)

CVE-2011-0096

CWE ID(s)

79

Security Risks

It is possible to steal or manipulate customer session and cookies, which might be used to impersonate a legitimate user, allowing the hacker to view or alter user records, and to perform transactions as that user

Possible Causes

Sanitation of hazardous characters was not performed correctly on user input

Technical Description

It has been found that the site is vulnerable to Windows MHTML Cross-Site Scripting. Below is the technical explanation of the MHTML Cross-Site Scripting attack, followed by a general review of the Cross-Site Scripting.
MHTML is a file format used by Microsoft Windows and Microsoft Internet Explorer for the purpose of archiving entire web sites. The MHTML handler may be prepended to web requests, forcing Internet Explorer to use the MHTML protocol.
Since Microsoft Windows is at fault, the version of Internet Explorer is not relevant.
The content of the MHTML file format resembles simple HTTP traffic. For example:
 From: <Saved by Windows Internet Explorer 8>
 Subject: IBM
 Date: Wed, 2 Feb 2011 13:58:08 +0200
 MIME-Version: 1.0
 Content-Type: multipart/related;
    type="text/html";
    boundary="----=_NextPart_000_0024_01CBC2E1.38BE5920"
 X-MimeOLE: Produced By Microsoft MimeOLE V6.00.2900.5994

 This is a multi-part message in MIME format.

 ------=_NextPart_000_0024_01CBC2E1.38BE5920
 Content-Type: text/html;
    charset="windows-1255"
 Content-Transfer-Encoding: quoted-printable
 Content-Location: http://www.ibm.com/index.html?param=AppScan

 <HTML>IBM's Website, Hello AppScan</HTML>
 Note: The content of the MHTML file above may also include binary data encoded in BASE64, as it is

encoded by MIME when using regular HTTP communication.

Consequently, even if an attacker is unable to inject JavaScript to the returned response of the site, due to restrictions and/or filtering, an attacker may be able to inject BASE64 content, since BASE64 isn't generally considered a threat. An attacker could inject BASE64 encoded JavaScript using the following payload:

Content-Type:%20multipart/related;%20boundary=_AppScan%0d%0a--_AppScan%0d%0aContent-Location:foo%0d%0aContent-Transfer-Encoding:base64%0d%0a%0d%0aPGh0bWw%2bPHNjcmlwdD5hbGVydCgiWFNTIik8L3NjcmlwdD48L2h0bWw%2b%0d%0a

The following request technique, located on the attacker's site, could be used:

<iframe src="MHTML:http://[SERVER]/index.php?param=Content-Type:%20multipart/related;%20boundary=_AppScan%0d%0a--_AppScan%0d%0aContent-Location:foo%0d%0aContent-Transfer-Encoding:base64%0d%0a%0d%0aPGh0bWw%2bPHNjcmlwdD5hbGVydCgiWFNTIik8L3NjcmlwdD48L2h0bWw%2b%0d%0a!foo"></iframe>

The payload decodes to:

Content-Type: multipart/related; boundary=_AppScan

--_AppScan

Content-Location:foo

Content-Transfer-Encoding:base64

PGh0bWw+PHNjcmlwdD5hbGVydCgiWFNTIik8L3NjcmlwdD48L2h0bWw+

Unless the "MHTML:" handler is prepended in the <iframe> tag above, the payload will be injected to the web site, but the BASE64 content will not be decoded by the client's browser. This is due to the behavior of the MHTML protocol mentioned above.

In the above payload the BASE64 data decodes to:

<html><script>alert("XSS")</script></html>

To conclude, the above attack revealed a Cross-Site Scripting vulnerability. This was done in the following sequence:

1. A client requested the attacker's site, which included an <iframe> tag containing a malicious request to the vulnerable site.

2. The <iframe> tag, including the "MHTML:" handler, was processed by the client's browser, upon which another request was made to the vulnerable site, this time including the malicious injection.

3. The malicious injection was successfully injected to the vulnerable web site and served as response to the client's browser.

4. The client's browser was forced to process the response data using the MHTML protocol, thus decoding the BASE64 information and running the malicious JavaScript code on the client-side machine.

The Cross-Site Scripting attack is a privacy violation, that allows an attacker to acquire a legitimate user's credentials and to impersonate that user when interacting with a specific website.

The attack hinges on the fact that the web site contains a script that returns a user's input (usually a parameter value) in an HTML page, without first sanitizing the input. This allows an input consisting of JavaScript code to be executed by the browser when the script returns this input in the response page. As a result, it is possible to form links to the site where one of the parameters consists of malicious JavaScript code. This code will be executed (by a user's browser) in the site context, granting it access to cookies that the user has for the site, and other windows in the site through the user's browser.

The attack proceeds as follows: The attacker lures the legitimate user to click on a link that was produced by the attacker. When the user clicks on the link, this generates a request to the web-site containing a parameter value with malicious JavaScript code. If the web-site embeds this parameter value into the response HTML page (this is the essence of the site issue), the malicious code will run in the user's browser.

Possible actions that can be performed by the script are:

[1] Send user's cookies (for the legitimate site) to the attacker.

[2] Send information that is accessible through the DOM (URLs, Form fields, etc.), to the attacker. The result is that the security and privacy of the victim user is compromised on the vulnerable site. Some notes:

[1] Although the attacked web site is involved, it is not compromised directly. It is used as a 'jump station' for the malicious script sent by the attacker, to return to the victim's browser, as if it is legitimate. However, since the privacy of the victim is breached in the context of the specific site, and since the site is directly responsible, it is considered a security flaw in the site.

[2] The malicious link can be provided by the attacker, using a web site link, if the attacker maintains a site that is visited by the victim user. The malicious link can also be provided by e-mail, if the attacker knows the user's e-mail address, and the user's e-mail client uses the browser to render the HTML message.

[3] While user input is most commonly found in form field values (i.e. URL parameters), there are known attacks where the malicious code is embedded in the path, query, or in the HTTP Referrer headers, and even in cookies.

[4] AppScan sends many types of Cross-Site Scripting attacks, including attacks that work only on specific browsers or versions of browsers. AppScan's "Show in Browser" feature uses Internet Explorer to show the vulnerability. In the case of variants to which Internet Explorer is not vulnerable, but other browsers are, the "Show in Browser" facility does not work and the popup is not shown.

The most basic cross-site scripting variants

There are two possible scenarios for sending input to a web application that is vulnerable to cross-site scripting:

A. The parameter value sent to the CGI script is returned in the response page, embedded in the HTML.
For example:
[request]
GET /cgi-bin/script.pl?name=JSmith HTTP/1.0
[response]
HTTP/1.1 200 OK
Server: SomeServer
Date: Sun, 01 Jan 2002 00:31:19 GMT
Content-Type: text/html
Accept-Ranges: bytes
Content-Length: 27
<HTML>
Hello JSmith
</HTML>

B. The parameter value sent to the CGI script is returned in an HTML parameter value context.
For example:
[request]
GET /cgi-bin/script.pl?name=JSmith HTTP/1.0
[response]
HTTP/1.1 200 OK
Server: SomeServer
Date: Sun, 01 Jan 2002 00:31:19 GMT
Content-Type: text/html
Accept-Ranges: bytes
Content-Length: 254
<HTML>
Please fill in your zip code:
<FORM METHOD=GET ACTION="/cgi-bin/script.pl">
<INPUT TYPE=text NAME="name" value="JSmith">
<INPUT TYPE=text NAME="zip" value="Enter zip code here">

```
<INPUT TYPE=submit value="Submit">
</FORM>
</HTML>
```
Example 1 - scenario A
The following request is sent by the user:
[attack request]
GET /cgi-bin/script.pl?name=<script>alert('Watchfire%20XSS%20Test%20Successful')</script>
HTTP/1.0
[attack response scenario A]
HTTP/1.1 200 OK
Server: SomeServer
Date: Sun, 01 Jan 2002 00:31:19 GMT
Content-Type: text/html
Accept-Ranges: bytes
Content-Length: 83
<HTML>
Hello <script>alert('Watchfire XSS Test Successful')</script>
</HTML>
In this case, the JavaScript code will be executed by the browser.

General Fix Recommendations

The attack vector utilizes the possibility of injecting newline characters. Therefore a workaround is to filter out newline characters in the input sent to the site (for example with %0d%0a). An attacker will then be unable to inject text resembling valid HTTP traffic data.

Another workaround is to prevent the browser from processing the response as MHTML. One way of achieving this could be by inserting an empty line in the response (possibly prepending a newline to beginning of the response), thus breaking the way that HTTP headers are read by the MHTML protocol. The empty line should be anywhere before the payload is injected.

More information about workarounds may be found Microsoft's Research and Defense blog:
http://blogs.technet.com/b/srd/archive/2011/01/28/more-information-about-the-mhtml-script-injection-vulnerability.aspx

SQL Injection

Application

WASC Threat Classification

SQL Injection

http://projects.webappsec.org/SQL-Injection

CVE ID(s)

N/A

CWE ID(s)

89

Security Risks

It is possible to view, modify or delete database entries and tables

Possible Causes

Sanitation of hazardous characters was not performed correctly on user input

Technical Description

The software constructs all or part of an SQL command using externally-influenced input, but it incorrectly neutralizes special elements that could modify the intended SQL command when sent to the database.

Without sufficient removal or quoting of SQL syntax in user-controllable inputs, the generated SQL query can cause those inputs to be interpreted as SQL instead of ordinary user data. This can be used to alter query logic to bypass security checks, or to insert additional statements that modify the back-end database, and possibly including execution of system commands.

For example, let's say we have an HTML page with a login form, which eventually runs the following SQL query on the database using the user input:

  SELECT * FROM accounts WHERE username='$user' AND password='$pass'

The two variables, $user and $pass, contain the user credentials entered by the user in the login form. Therefore, if the user has input "jsmith" as the username, and "Demo1234" as the password, the SQL query will look like this:

  SELECT * FROM accounts WHERE username='jsmith' AND password='Demo1234'

But if the user input "'" (a single apostrophe) as the username, and "'" (a single apostrophe) as the password, the SQL query will look like this:

  SELECT * FROM accounts WHERE username=''' AND password='''

This, of course, is a malformed SQL query, and will invoke an error message, which may be returned in the HTTP response.

An error such as this informs the attacker that an SQL Injection has succeeded, which will lead the attacker to attempt further attack vectors.

Sample Exploit:

The following C# code dynamically constructs and executes a SQL query that searches for items matching a specified name. The query restricts the items displayed to those where owner matches the user name of the currently-authenticated user.

  …
  string userName = ctx.getAuthenticatedUserName();
  string query = "SELECT * FROM items WHERE owner = ""

```
                    + userName + "' AND itemname = '"
                    + ItemName.Text + "'";
  sda = new SqlDataAdapter(query, conn);
  DataTable dt = new DataTable();
  sda.Fill(dt);
  …
```
The query that this code intends to execute follows:
  SELECT * FROM items WHERE owner = AND itemname = ;
However, because the query is constructed dynamically by concatenating a constant base query string and a user input string, the query only behaves correctly if itemName does not contain a single-quote character. If an attacker with the user name wiley enters the string "name' OR 'a'='a" for itemName, then the query becomes the following:
  SELECT * FROM items WHERE owner = 'wiley' AND itemname = 'name' OR 'a'='a';
The addition of the OR 'a'='a' condition causes the where clause to always evaluate to true, so the query becomes logically equivalent to the much simpler query:
  SELECT * FROM items;

General Fix Recommendations

There are several mitigation techniques:
[1] Strategy: Libraries or Frameworks
Use a vetted library or framework that does not allow this weakness to occur, or provides constructs that make it easier to avoid.
[2] Strategy: Parameterization
If available, use structured mechanisms that automatically enforce the separation between data and code. These mechanisms may be able to provide the relevant quoting, encoding, and validation automatically, instead of relying on the developer to provide this capability at every point where output is generated.
[3] Strategy: Environment Hardening
Run your code using the lowest privileges that are required to accomplish the necessary tasks.
[4] Strategy: Output Encoding
If you need to use dynamically-generated query strings or commands in spite of the risk, properly quote arguments and escape any special characters within those arguments.
[5] Strategy: Input Validation
Assume all input is malicious. Use an "accept known good" input validation strategy: a whitelist of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. Do not rely exclusively on blacklisting malicious or malformed inputs. However, blacklists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

J2EE Fix Recommendations

** Prepared Statements:
There are 3 possible ways to protect your application against SQL injection, i.e. malicious tampering of SQL parameters. Instead of dynamically building SQL statements, use:
[1] PreparedStatement, which is precompiled and stored in a pool of PreparedStatement objects. PreparedStatement defines setters to register input parameters that are compatible with the supported JDBC SQL data types. For example, setString should be used for input parameters of type VARCHAR or LONGVARCHAR (refer to the Java API for further details). This way of setting input parameters prevents an attacker from manipulating the SQL statement through injection of bad

```

characters, such as apostrophe.
Example of how to use a PreparedStatement in J2EE:

```
 // J2EE PreparedStatemenet Example
 // Get a connection to the database
 Connection myConnection;
 if (isDataSourceEnabled()) {
    // using the DataSource to get a managed connection
    Context ctx = new InitialContext();
    myConnection = ((DataSource)ctx.lookup(datasourceName)).getConnection(dbUserName,
dbPassword);
 } else {
    try {
       // using the DriverManager to get a JDBC connection
       Class.forName(jdbcDriverClassPath);
       myConnection = DriverManager.getConnection(jdbcURL, dbUserName, dbPassword);
    } catch (ClassNotFoundException e) {
       ...
    }
 }
 ...
 try {
    PreparedStatement myStatement = myConnection.prepareStatement("select * from users where
username = ?");
    myStatement.setString(1, userNameField);
    ResultSet rs = myStatement.executeQuery();

    ...
    rs.close();
 } catch (SQLException sqlException) {

    ...
 } finally {
    myStatement.close();
    myConnection.close();
 }
```

[2] CallableStatement, which extends PreparedStatement to execute database SQL stored
procedures. This class inherits input setters from PreparedStatement (see [1] above).
The following example assumes that this database stored procedure has been created:
CREATE PROCEDURE select_user (@username varchar(20))
AS SELECT * FROM USERS WHERE USERNAME = @username;
Example of how to use a CallableStatement in J2EE to execute the above stored procedure:

```
 // J2EE PreparedStatemenet Example
 // Get a connection to the database
 Connection myConnection;
 if (isDataSourceEnabled()) {
    // using the DataSource to get a managed connection
    Context ctx = new InitialContext();
    myConnection = ((DataSource)ctx.lookup(datasourceName)).getConnection(dbUserName,
dbPassword);
 } else {
    try {
       // using the DriverManager to get a JDBC connection
       Class.forName(jdbcDriverClassPath);
       myConnection = DriverManager.getConnection(jdbcURL, dbUserName, dbPassword);
    } catch (ClassNotFoundException e) {
```

```
        ...
    }
  }
  ...
  try {
      PreparedStatement myStatement = myConnection.prepareCall("{?= call select_user ?,?}");
      myStatement.setString(1, userNameField);
      myStatement.registerOutParameter(1, Types.VARCHAR);
      ResultSet rs = myStatement.executeQuery();

      ...
      rs.close();
  } catch (SQLException sqlException) {

      ...
  } finally {
      myStatement.close();
      myConnection.close();
  }
```

[3] Entity Bean, which represents an EJB business object in a persistent storage mechanism. There are two types of entity beans: bean-managed and container-managed. With bean-managed persistence, the developer is responsible of writing the SQL code to access the database (refer to sections [1] and [2] above). With container-managed persistence, the EJB container automatically generates the SQL code. As a result, the container is responsible of preventing malicious attempts to tamper with the generated SQL code.

Example of how to use an Entity Bean in J2EE:

```
  // J2EE EJB Example
  try {
      // lookup the User home interface
      UserHome userHome = (UserHome)context.lookup(User.class);
      // find the User remote interface
      User = userHome.findByPrimaryKey(new UserKey(userNameField));

      ...
  } catch (Exception e) {

      ...
  }
```

** Input Data Validation:
While data validations may be provided as a user convenience on the client-tier, data validation must be performed on the server-tier using Servlets. Client-side validations are inherently insecure because they can be easily bypassed, e.g. by disabling Javascript.

A good design usually requires the web application framework to provide server-side utility routines to validate the following:
[1] Required field
[2] Field data type (all HTTP request parameters are Strings by default)
[3] Field length
[4] Field range
[5] Field options
[6] Field pattern
[7] Cookie values
[8] HTTP Response

A good practice is to implement the above routine as static methods in a "Validator" utility class. The following sections describe an example validator class.

[1] Required field

Always check that the field is not null and its length is greater than zero, excluding leading and trailing white spaces.

Example of how to validate required fields:

```java
// Java example to validate required fields
public Class Validator {
    ...
    public static boolean validateRequired(String value) {
        boolean isFieldValid = false;
        if (value != null && value.trim().length() > 0) {
            isFieldValid = true;
        }
        return isFieldValid;
    }
    ...
}
...
String fieldValue = request.getParameter("fieldName");
if (Validator.validateRequired(fieldValue)) {
    // fieldValue is valid, continue processing request
    ...
}
```

[2] Field data type

In web applications, input parameters are poorly typed. For example, all HTTP request parameters or cookie values are of type String. The developer is responsible for verifying the input is of the correct data type. Use the Java primitive wrapper classes to check if the field value can be safely converted to the desired primitive data type.

Example of how to validate a numeric field (type int):

```java
// Java example to validate that a field is an int number
public Class Validator {
    ...
    public static boolean validateInt(String value) {
        boolean isFieldValid = false;
        try {
            Integer.parseInt(value);
            isFieldValid = true;
        } catch (Exception e) {
            isFieldValid = false;
        }
        return isFieldValid;
    }
    ...
}
...
// check if the HTTP request parameter is of type int
String fieldValue = request.getParameter("fieldName");
if (Validator.validateInt(fieldValue)) {
    // fieldValue is valid, continue processing request
    ...
}
```

A good practice is to convert all HTTP request parameters to their respective data types. For

example, the developer should store the "integerValue" of a request parameter in a request attribute and use it as shown in the following example:

```
// Example to convert the HTTP request parameter to a primitive wrapper data type
// and store this value in a request attribute for further processing
String fieldValue = request.getParameter("fieldName");
if (Validator.validateInt(fieldValue)) {
    // convert fieldValue to an Integer
    Integer integerValue = Integer.getInteger(fieldValue);
    // store integerValue in a request attribute
    request.setAttribute("fieldName", integerValue);
}
...
// Use the request attribute for further processing
Integer integerValue = (Integer)request.getAttribute("fieldName");
...
```

The primary Java data types that the application should handle:
- Byte
- Short
- Integer
- Long
- Float
- Double
- Date

[3] Field length

Always ensure that the input parameter (whether HTTP request parameter or cookie value) is bounded by a minimum length and/or a maximum length.

Example to validate that the length of the userName field is between 8 and 20 characters:

```
// Example to validate the field length
public Class Validator {
    ...
    public static boolean validateLength(String value, int minLength, int maxLength) {
        String validatedValue = value;
        if (!validateRequired(value)) {
            validatedValue = "";
        }
        return (validatedValue.length() >= minLength &&
                validatedValue.length() <= maxLength);
    }
    ...
}
...
String userName = request.getParameter("userName");
if (Validator.validateRequired(userName)) {
    if (Validator.validateLength(userName, 8, 20)) {
        // userName is valid, continue further processing
        ...
    }
}
```

[4] Field range

Always ensure that the input parameter is within a range as defined by the functional requirements.

Example to validate that the input numberOfChoices is between 10 and 20:

```
// Example to validate the field range
public Class Validator {
```

```
    ...
    public static boolean validateRange(int value, int min, int max) {
        return (value >= min && value <= max);
    }
    ...
}
...
String fieldValue = request.getParameter("numberOfChoices");
if (Validator.validateRequired(fieldValue)) {
    if (Validator.validateInt(fieldValue)) {
        int numberOfChoices = Integer.parseInt(fieldValue);
        if (Validator.validateRange(numberOfChoices, 10, 20)) {
            // numberOfChoices is valid, continue processing request
            ...
        }
    }
}
```

[5] Field options

Often, the web application presents the user with a set of options to choose from, e.g. using the SELECT HTML tag, but fails to perform server-side validation to ensure that the selected value is one of the allowed options. Remember that a malicious user can easily modify any option value. Always validate the selected user value against the allowed options as defined by the functional requirements. Example to validate the user selection against a list of allowed options:

```
// Example to validate user selection against a list of options
public Class Validator {

    ...
    public static boolean validateOption(Object[] options, Object value) {
        boolean isValidValue = false;
        try {
            List list = Arrays.asList(options);
            if (list != null) {
                isValidValue = list.contains(value);
            }
        } catch (Exception e) {
        }
        return isValidValue;
    }
    ...
}
...
// Allowed options
String[] options = {"option1", "option2", "option3");
// Verify that the user selection is one of the allowed options
String userSelection = request.getParameter("userSelection");
if (Validator.validateOption(options, userSelection)) {
    // valid user selection, continue processing request
    ...
}
```

[6] Field pattern

Always check that the user input matches a pattern as defined by the functionality requirements. For example, if the userName field should only allow alpha-numeric characters, case insensitive, then use the following regular expression:

^[a-zA-Z0-9]*$

Java 1.3 or earlier versions do not include any regular expression packages. Apache Regular Expression Package (see Resources below) is recommended for use with Java 1.3 to resolve this lack of support. Example to perform regular expression validation:

```
// Example to validate that a given value matches a specified pattern
// using the Apache regular expression package
import org.apache.regexp.RE;
import org.apache.regexp.RESyntaxException;
public Class Validator {
    ...
    public static boolean matchPattern(String value, String expression) {
        boolean match = false;
        if (validateRequired(expression)) {
            RE r = new RE(expression);
            match = r.match(value);
        }
        return match;
    }
    ...
}
...
// Verify that the userName request parameter is alpha-numeric
String userName = request.getParameter("userName");
if (Validator.matchPattern(userName, "^[a-zA-Z0-9]*$")) {
    // userName is valid, continue processing request
    ...
}
```

Java 1.4 introduced a new regular expression package (java.util.regex). Here is a modified version of Validator.matchPattern using the new Java 1.4 regular expression package:

```
// Example to validate that a given value matches a specified pattern
// using the Java 1.4 regular expression package
import java.util.regex.Pattern;
import java.util.regexe.Matcher;
public Class Validator {
    ...
    public static boolean matchPattern(String value, String expression) {
        boolean match = false;
        if (validateRequired(expression)) {
            match = Pattern.matches(expression, value);
        }
        return match;
    }
    ...
}
```

[7] Cookie value
Use the javax.servlet.http.Cookie object to validate the cookie value. The same validation rules (described above) apply to cookie values depending on the application requirements, e.g. validate a required value, validate length, etc.
Example to validate a required cookie value:

```
// Example to validate a required cookie value
// First retrieve all available cookies submitted in the HTTP request
Cookie[] cookies = request.getCookies();
if (cookies != null) {
    // find the "user" cookie
```

```
        for (int i=0; i<cookies.length; ++i) {
            if (cookies[i].getName().equals("user")) {
                // validate the cookie value
                if (Validator.validateRequired(cookies[i].getValue()) {
                    // valid cookie value, continue processing request
                    ...
                }
            }
        }
    }
```

[8] HTTP Response

[8-1] Filter user input

To guard the application against cross-site scripting, sanitize HTML by converting sensitive characters to their corresponding character entities. These are the HTML sensitive characters:

< > " ' % ;) (& +

Example to filter a specified string by converting sensitive characters to their corresponding character entities:

```
 // Example to filter sensitive data to prevent cross-site scripting
 public Class Validator {
    ...
    public static String filter(String value) {
        if (value == null) {
            return null;
        }
        StringBuffer result = new StringBuffer(value.length());
        for (int i=0; i<value.length(); ++i) {
            switch (value.charAt(i)) {
            case '<':
                result.append("&lt;");
                break;
            case '>':
                result.append("&gt;");
                break;
            case '"':
                result.append("&quot;");
                break;
            case '\'':
                result.append("&#39;");
                break;
            case '%':
                result.append("&#37;");
                break;
            case ';':
                result.append("&#59;");
                break;
            case '(':
                result.append("&#40;");
                break;
            case ')':
                result.append("&#41;");
                break;
            case '&':
                result.append("&amp;");
```

```
                break;
             case '+':
                result.append("&#43;");
                break;
             default:
                result.append(value.charAt(i));
                break;
         }
         return result;
      }
      ...
   }
   ...
   // Filter the HTTP response using Validator.filter
   PrintWriter out = response.getWriter();
   // set output response
   out.write(Validator.filter(response));
   out.close();
```

The Java Servlet API 2.3 introduced Filters, which supports the interception and transformation of HTTP requests or responses.

Example of using a Servlet Filter to sanitize the response using Validator.filter:

```
   // Example to filter all sensitive characters in the HTTP response using a Java Filter.
   // This example is for illustration purposes since it will filter all content in the response, including
   HTML tags!
   public class SensitiveCharsFilter implements Filter {
      ...
      public void doFilter(ServletRequest request,
                  ServletResponse response,
                  FilterChain chain)
         throws IOException, ServletException {

         PrintWriter out = response.getWriter();
         ResponseWrapper wrapper = new ResponseWrapper((HttpServletResponse)response);
         chain.doFilter(request, wrapper);

         CharArrayWriter caw = new CharArrayWriter();
         caw.write(Validator.filter(wrapper.toString()));

         response.setContentType("text/html");
         response.setContentLength(caw.toString().length());
         out.write(caw.toString());
         out.close();
      }
      ...
      public class CharResponseWrapper extends HttpServletResponseWrapper {
         private CharArrayWriter output;

         public String toString() {
            return output.toString();
         }

         public CharResponseWrapper(HttpServletResponse response){
            super(response);
```

```
            output = new CharArrayWriter();
        }

        public PrintWriter getWriter(){
            return new PrintWriter(output);
        }
    }
  }

  }
```
[8-2] Secure the cookie
When storing sensitive data in a cookie, make sure to set the secure flag of the cookie in the HTTP response, using Cookie.setSecure(boolean flag) to instruct the browser to send the cookie using a secure protocol, such as HTTPS or SSL.
Example to secure the "user" cookie:
```
  // Example to secure a cookie, i.e. instruct the browser to
  // send the cookie using a secure protocol
  Cookie cookie = new Cookie("user", "sensitive");
  cookie.setSecure(true);
  response.addCookie(cookie);
```
RECOMMENDED JAVA TOOLS
The two main Java frameworks for server-side validation are:
[1] Jakarta Commons Validator (integrated with Struts 1.1)
The Jakarta Commons Validator is a powerful framework that implements all the above data validation requirements. These rules are configured in an XML file that defines input validation rules for form fields. Struts supports output filtering of dangerous characters in the [8] HTTP Response by default on all data written using the Struts 'bean:write' tag. This filtering may be disabled by setting the 'filter=false' flag.
Struts defines the following basic input validators, but custom validators may also be defined:
required: succeeds if the field contains any characters other than white space.
mask: succeeds if the value matches the regular expression given by the mask attribute.
range: succeeds if the value is within the values given by the min and max attributes ((value >= min) & (value <= max)).
maxLength: succeeds if the field is length is less than or equal to the max attribute.
minLength: succeeds if the field is length is greater than or equal to the min attribute.
byte, short, integer, long, float, double: succeeds if the value can be converted to the corresponding primitive.
date: succeeds if the value represents a valid date. A date pattern may be provided.
creditCard: succeeds if the value could be a valid credit card number.
e-mail: succeeds if the value could be a valid e-mail address.
Example to validate the userName field of a loginForm using Struts Validator:
```
  <form-validation>
    <global>
        ...
      <validator name="required"
         classname="org.apache.struts.validator.FieldChecks"
         method="validateRequired"
         msg="errors.required">
      </validator>
      <validator name="mask"
         classname="org.apache.struts.validator.FieldChecks"
         method="validateMask"
         msg="errors.invalid">
```

```
          </validator>
          ...
      </global>
      <formset>
        <form name="loginForm">
          <!-- userName is required and is alpha-numeric case insensitive -->
          <field property="userName" depends="required,mask">
            <!-- message resource key to display if validation fails -->
            <msg name="mask" key="login.userName.maskmsg"/>
            <arg0 key="login.userName.displayname"/>
            <var>
              <var-name>mask</var-name>
              <var-value>^[a-zA-Z0-9]*$</var-value>
            </var>
          </field>
          ...
        </form>
        ...
      </formset>
  </form-validation>
```

[2] JavaServer Faces Technology

JavaServer Faces Technology is a set of Java APIs (JSR 127) to represent UI components, manage their state, handle events and input validation.

The JavaServer Faces API implements the following basic validators, but custom validators may be defined:

validate_doublerange: registers a DoubleRangeValidator on a component

validate_length: registers a LengthValidator on a component

validate_longrange: registers a LongRangeValidator on a component

validate_required: registers a RequiredValidator on a component

validate_stringrange: registers a StringRangeValidator on a component

validator: registers a custom Validator on a component

The JavaServer Faces API defines the following UIInput and UIOutput Renderers (Tags):

input_date: accepts a java.util.Date formatted with a java.text.Date instance

output_date: displays a java.util.Date formatted with a java.text.Date instance

input_datetime: accepts a java.util.Date formatted with a java.text.DateTime instance

output_datetime: displays a java.util.Date formatted with a java.text.DateTime instance

input_number: displays a numeric data type (java.lang.Number or primitive), formatted with a java.text.NumberFormat

output_number: displays a numeric data type (java.lang.Number or primitive), formatted with a java.text.NumberFormat

input_text: accepts a text string of one line.

output_text: displays a text string of one line.

input_time: accepts a java.util.Date, formatted with a java.text.DateFormat time instance

output_time: displays a java.util.Date, formatted with a java.text.DateFormat time instance

input_hidden: allows a page author to include a hidden variable in a page

input_secret: accepts one line of text with no spaces and displays it as a set of asterisks as it is typed

input_textarea: accepts multiple lines of text

output_errors: displays error messages for an entire page or error messages associated with a specified client identifier

output_label: displays a nested component as a label for a specified input field

output_message: displays a localized message

Example to validate the userName field of a loginForm using JavaServer Faces:

```
<%@ taglib uri="http://java.sun.com/jsf/html" prefix="h" %>
<%@ taglib uri="http://java.sun.com/jsf/core" prefix="f" %>
...
<jsp:useBean id="UserBean"
    class="myApplication.UserBean" scope="session" />
<f:use_faces>
  <h:form formName="loginForm" >
    <h:input_text id="userName" size="20" modelReference="UserBean.userName">
       <f:validate_required/>
       <f:validate_length minimum="8" maximum="20"/>
    </h:input_text>
    <!-- display errors if present -->
    <h:output_errors id="loginErrors" clientId="userName"/>
    <h:command_button id="submit" label="Submit" commandName="submit" /><p>
  </h:form>
</f:use_faces>
```

** Error Handling:

Many J2EE web application architectures follow the Model View Controller (MVC) pattern. In this pattern a Servlet acts as a Controller. A Servlet delegates the application processing to a JavaBean such as an EJB Session Bean (the Model). The Servlet then forwards the request to a JSP (View) to render the processing results. Servlets should check all input, output, return codes, error codes and known exceptions to ensure that the expected processing actually occurred.

While data validation protects applications against malicious data tampering, a sound error handling strategy is necessary to prevent the application from inadvertently disclosing internal error messages such as exception stack traces. A good error handling strategy addresses the following items:

[1] Defining Errors

[2] Reporting Errors

[3] Rendering Errors

[4] Error Mapping

[1] Defining Errors

Hard-coded error messages in the application layer (e.g. Servlets) should be avoided. Instead, the application should use error keys that map to known application failures. A good practice is to define error keys that map to validation rules for HTML form fields or other bean properties. For example, if the "user_name" field is required, is alphanumeric, and must be unique in the database, then the following error keys should be defined:

(a) ERROR_USERNAME_REQUIRED: this error key is used to display a message notifying the user that the "user_name" field is required;

(b) ERROR_USERNAME_ALPHANUMERIC: this error key is used to display a message notifying the user that the "user_name" field should be alphanumeric;

(c) ERROR_USERNAME_DUPLICATE: this error key is used to display a message notifying the user that the "user_name" value is a duplicate in the database;
(d) ERROR_USERNAME_INVALID: this error key is used to display a generic message notifying the user that the "user_name" value is invalid;
A good practice is to define the following framework Java classes which are used to store and report application errors:
- ErrorKeys: defines all error keys

```
    // Example: ErrorKeys defining the following error keys:
    //   - ERROR_USERNAME_REQUIRED
    //   - ERROR_USERNAME_ALPHANUMERIC
    //   - ERROR_USERNAME_DUPLICATE
    //   - ERROR_USERNAME_INVALID
    //   ...
    public Class ErrorKeys {
       public static final String ERROR_USERNAME_REQUIRED = "error.username.required";
       public static final String ERROR_USERNAME_ALPHANUMERIC =
"error.username.alphanumeric";
       public static final String ERROR_USERNAME_DUPLICATE = "error.username.duplicate";
       public static final String ERROR_USERNAME_INVALID = "error.username.invalid";
       ...
    }
```

- Error: encapsulates an individual error

```
    // Example: Error encapsulates an error key.
    // Error is serializable to support code executing in multiple JVMs.
    public Class Error implements Serializable {

       // Constructor given a specified error key
       public Error(String key) {
          this(key, null);
       }

       // Constructor given a specified error key and array of placeholder objects
       public Error(String key, Object[] values) {
          this.key = key;
          this.values = values;
       }

       // Returns the error key
       public String getKey() {
          return this.key;
       }

       // Returns the placeholder values
       public Object[] getValues() {
          return this.values;
       }

       private String key = null;
       private Object[] values = null;
    }
```

- Errors: encapsulates a Collection of errors

```
    // Example: Errors encapsulates the Error objects being reported to the presentation layer.
    // Errors are stored in a HashMap where the key is the bean property name and value is an
```

```java
// ArrayList of Error objects.
public Class Errors implements Serializable {

    // Adds an Error object to the Collection of errors for the specified bean property.
    public void addError(String property, Error error) {
        ArrayList propertyErrors = (ArrayList)errors.get(property);
        if (propertyErrors == null) {
            propertyErrors = new ArrayList();
            errors.put(property, propertyErrors);
        }
        propertyErrors.put(error);
    }

    // Returns true if there are any errors
    public boolean hasErrors() {
        return (errors.size > 0);
    }

    // Returns the Errors for the specified property
    public ArrayList getErrors(String property) {
        return (ArrayList)errors.get(property);
    }

    private HashMap errors = new HashMap();
}
```
Using the above framework classes, here is an example to process validation errors of the "user_name" field:
```java
// Example to process validation errors of the "user_name" field.
Errors errors = new Errors();
String userName = request.getParameter("user_name");
// (a) Required validation rule
if (!Validator.validateRequired(userName)) {
    errors.addError("user_name", new Error(ErrorKeys.ERROR_USERNAME_REQUIRED));
} // (b) Alpha-numeric validation rule
else if (!Validator.matchPattern(userName, "^[a-zA-Z0-9]*$")) {
    errors.addError("user_name", new Error(ErrorKeys.ERROR_USERNAME_ALPHANUMERIC));
}
else
{
    // (c) Duplicate check validation rule
    // We assume that there is an existing UserValidationEJB session bean that implements
    // a checkIfDuplicate() method to verify if the user already exists in the database.
    try {
        ...
        if (UserValidationEJB.checkIfDuplicate(userName)) {
            errors.addError("user_name", new Error(ErrorKeys.ERROR_USERNAME_DUPLICATE));
        }
    } catch (RemoteException e) {
        // log the error
        logger.error("Could not validate user for specified userName: " + userName);
        errors.addError("user_name", new Error(ErrorKeys.ERROR_USERNAME_DUPLICATE);
    }
}
```

```
   // set the errors object in a request attribute called "errors"
   request.setAttribute("errors", errors);
    ...
```
[2] Reporting Errors

There are two ways to report web-tier application errors:

(a) Servlet Error Mechanism

(b) JSP Error Mechanism

[2-a] Servlet Error Mechanism

A Servlet may report errors by:

- forwarding to the input JSP (having already stored the errors in a request attribute), OR
- calling response.sendError with an HTTP error code argument, OR
- throwing an exception

It is good practice to process all known application errors (as described in section [1]), store them in a request attribute, and forward to the input JSP. The input JSP should display the error messages and prompt the user to re-enter the data. The following example illustrates how to forward to an input JSP (userInput.jsp):

```
   // Example to forward to the userInput.jsp following user validation errors
   RequestDispatcher rd = getServletContext().getRequestDispatcher("/user/userInput.jsp");
   if (rd != null) {
       rd.forward(request, response);
   }
```

If the Servlet cannot forward to a known JSP page, the second option is to report an error using the response.sendError method with HttpServletResponse.SC_INTERNAL_SERVER_ERROR (status code 500) as argument. Refer to the javadoc of javax.servlet.http.HttpServletResponse for more details on the various HTTP status codes. Example to return a HTTP error:

```
   // Example to return a HTTP error code
   RequestDispatcher rd = getServletContext().getRequestDispatcher("/user/userInput.jsp");
   if (rd == null) {
       // messages is a resource bundle with all message keys and values
       response.sendError(HttpServletResponse.SC_INTERNAL_SERVER_ERROR,
                 messages.getMessage(ErrorKeys.ERROR_USERNAME_INVALID));
   }
```

As a last resort, Servlets can throw an exception, which must be a subclass of one of the following classes:

- RuntimeException
- ServletException
- IOException

[2-b] JSP Error Mechanism

JSP pages provide a mechanism to handle runtime exceptions by defining an errorPage directive as shown in the following example:

```
     <%@ page errorPage="/errors/userValidation.jsp" %>
```

Uncaught JSP exceptions are forwarded to the specified errorPage, and the original exception is set in a request parameter called javax.servlet.jsp.jspException. The error page must include a isErrorPage directive as shown below:

```
     <%@ page isErrorPage="true" %>
```

The isErrorPage directive causes the "exception" variable to be initialized to the exception object being thrown.

[3] Rendering Errors

The J2SE Internationalization APIs provide utility classes for externalizing application resources and formatting messages including:

(a) Resource Bundles

(b) Message Formatting

[3-a] Resource Bundles
Resource bundles support internationalization by separating localized data from the source code that uses it. Each resource bundle stores a map of key/value pairs for a specific locale.
It is common to use or extend java.util.PropertyResourceBundle, which stores the content in an external properties file as shown in the following example:

```
################################################
# ErrorMessages.properties
################################################
# required user name error message
error.username.required=User name field is required

# invalid user name format
error.username.alphanumeric=User name must be alphanumeric

# duplicate user name error message
error.username.duplicate=User name {0} already exists, please choose another one

...
```

Multiple resources can be defined to support different locales (hence the name resource bundle). For example, ErrorMessages_fr.properties can be defined to support the French member of the bundle family. If the resource member of the requested locale does not exist, the default member is used. In the above example, the default resource is ErrorMessages.properties. Depending on the user's locale, the application (JSP or Servlet) retrieves content from the appropriate resource.
[3-b] Message Formatting
The J2SE standard class java.util.MessageFormat provides a generic way to create messages with replacement placeholders. A MessageFormat object contains a pattern string with embedded format specifiers as shown below:

```
// Example to show how to format a message using placeholder parameters
String pattern = "User name {0} already exists, please choose another one";
String userName = request.getParameter("user_name");
Object[] args = new Object[1];
args[0] = userName;
String message = MessageFormat.format(pattern, args);
```

Here is a more comprehensive example to render error messages using ResourceBundle and MessageFormat:

```
// Example to render an error message from a localized ErrorMessages resource (properties file)
// Utility class to retrieve locale-specific error messages
public Class ErrorMessageResource {

   // Returns the error message for the specified error key in the environment locale
   public String getErrorMessage(String errorKey) {
      return getErrorMessage(errorKey, defaultLocale);
   }

   // Returns the error message for the specified error key in the specified locale
   public String getErrorMessage(String errorKey, Locale locale) {
      return getErrorMessage(errorKey, null, locale);
   }

   // Returns a formatted error message for the specified error key in the specified locale
   public String getErrorMessage(String errorKey, Object[] args, Locale locale) {
      // Get localized ErrorMessageResource
      ResourceBundle errorMessageResource = ResourceBundle.getBundle("ErrorMessages",
```

```
locale);
        // Get localized error message
        String errorMessage = errorMessageResource.getString(errorKey);
        if (args != null) {
           // Format the message using the specified placeholders args
           return MessageFormat.format(errorMessage, args);
        } else {
           return errorMessage;
        }
     }

     // default environment locale
     private Locale defaultLocale = Locale.getDefaultLocale();
  }
  ...
  // Get the user's locale
  Locale userLocale = request.getLocale();
  // Check if there were any validation errors
  Errors errors = (Errors)request.getAttribute("errors");
  if (errors != null && errors.hasErrors()) {
     // iterate through errors and output error messages corresponding to the "user_name" property
     ArrayList userNameErrors = errors.getErrors("user_name");
     ListIterator iterator = userNameErrors.iterator();
     while (iterator.hasNext()) {
        // Get the next error object
        Error error = (Error)iterator.next();
        String errorMessage = ErrorMessageResource.getErrorMessage(error.getKey(), userLocale);
        output.write(errorMessage + "\r\n");
     }
  }
```

It is recommended to define a custom JSP tag, e.g. displayErrors, to iterate through and render error messages as shown in the above example.

[4] Error Mapping

Normally, the Servlet Container will return a default error page corresponding to either the response status code or the exception. A mapping between the status code or the exception and a web resource may be specified using custom error pages. It is a good practice to develop static error pages that do not disclose internal error states (by default, most Servlet containers will report internal error messages). This mapping is configured in the Web Deployment Descriptor (web.xml) as specified in the following example:

```
<!-- Mapping of HTTP error codes and application exceptions to error pages -->
<error-page>
  <exception-type>UserValidationException</exception-type>
  <location>/errors/validationError.html</error-page>
</error-page>
<error-page>
  <error-code>500</exception-type>
  <location>/errors/internalError.html</error-page>
</error-page>
<error-page>
...
</error-page>
...
```

RECOMMENDED JAVA TOOLS

The two main Java frameworks for server-side validation are:

[1] Jakarta Commons Validator (integrated with Struts 1.1)

The Jakarta Commons Validator is a Java framework that defines the error handling mechanism as described above. Validation rules are configured in an XML file that defines input validation rules for form fields and the corresponding validation error keys. Struts provides internationalization support to build localized applications using resource bundles and message formatting.

Example to validate the userName field of a loginForm using Struts Validator:

```
<form-validation>
  <global>
    ...
    <validator name="required"
      classname="org.apache.struts.validator.FieldChecks"
      method="validateRequired"
      msg="errors.required">
    </validator>
    <validator name="mask"
      classname="org.apache.struts.validator.FieldChecks"
      method="validateMask"
      msg="errors.invalid">
    </validator>
    ...
  </global>
  <formset>
    <form name="loginForm">
      <!-- userName is required and is alpha-numeric case insensitive -->
      <field property="userName" depends="required,mask">
        <!-- message resource key to display if validation fails -->
        <msg name="mask" key="login.userName.maskmsg"/>
        <arg0 key="login.userName.displayname"/>
        <var>
          <var-name>mask</var-name>
          <var-value>^[a-zA-Z0-9]*$</var-value>
        </var>
      </field>
      ...
    </form>
    ...
  </formset>
</form-validation>
```

The Struts JSP tag library defines the "errors" tag that conditionally displays a set of accumulated error messages as shown in the following example:

```
<%@ page language="java" %>
<%@ taglib uri="/WEB-INF/struts-html.tld" prefix="html" %>
<%@ taglib uri="/WEB-INF/struts-bean.tld" prefix="bean" %>
<html:html>
<head>
<body>
    <html:form action="/logon.do">
    <table border="0" width="100%">
    <tr>
      <th align="right">
        <html:errors property="username"/>
        <bean:message key="prompt.username"/>
```

```
        </th>
        <td align="left">
           <html:text property="username" size="16"/>
        </td>
     </tr>
     <tr>
     <td align="right">
        <html:submit><bean:message key="button.submit"/></html:submit>
     </td>
     <td align="right">
        <html:reset><bean:message key="button.reset"/></html:reset>
     </td>
     </tr>
     </table>
     </html:form>
  </body>
  </html:html>
```

[2] JavaServer Faces Technology

JavaServer Faces Technology is a set of Java APIs (JSR 127) to represent UI components, manage their state, handle events, validate input, and support internationalization.

The JavaServer Faces API defines the "output_errors" UIOutput Renderer, which displays error messages for an entire page or error messages associated with a specified client identifier.

Example to validate the userName field of a loginForm using JavaServer Faces:

```
  <%@ taglib uri="http://java.sun.com/jsf/html" prefix="h" %>
  <%@ taglib uri="http://java.sun.com/jsf/core" prefix="f" %>
  ...
  <jsp:useBean id="UserBean"
     class="myApplication.UserBean" scope="session" />
  <f:use_faces>
    <h:form formName="loginForm" >
      <h:input_text id="userName" size="20" modelReference="UserBean.userName">
         <f:validate_required/>
         <f:validate_length minimum="8" maximum="20"/>
      </h:input_text>
      <!-- display errors if present -->
      <h:output_errors id="loginErrors" clientId="userName"/>
      <h:command_button id="submit" label="Submit" commandName="submit" /><p>
    </h:form>
  </f:use_faces>
```

.Net Fix Recommendations

Here are two possible ways to protect your web application against SQL injection attacks:
[1] Use a stored procedure rather than dynamically built SQL query string. The way parameters are passed to SQL Server stored procedures, prevents the use of apostrophes and hyphens.
Here is a simple example of how to use stored procedures in ASP.NET:

```
' Visual Basic example
Dim DS As DataSet
Dim MyConnection As SqlConnection
Dim MyCommand As SqlDataAdapter

Dim SelectCommand As String = "select * from users where username = @username"
...
MyCommand.SelectCommand.Parameters.Add(New SqlParameter("@username",
SqlDbType.NVarChar, 20))
MyCommand.SelectCommand.Parameters("@username").Value = UserNameField.Value
```

```
// C# example
String selectCmd = "select * from Authors where state = @username";
SqlConnection myConnection = new SqlConnection("server=...");
SqlDataAdapter myCommand = new SqlDataAdapter(selectCmd, myConnection);

myCommand.SelectCommand.Parameters.Add(new SqlParameter("@username",
SqlDbType.NVarChar, 20));
myCommand.SelectCommand.Parameters["@username"].Value = UserNameField.Value;
```

[2] You can add input validation to Web Forms pages by using validation controls. Validation controls provide an easy-to-use mechanism for all common types of standard validation - for example, testing for valid dates or values within a range - plus ways to provide custom-written validation. In addition, validation controls allow you to completely customize how error information is displayed to the user. Validation controls can be used with any controls that are processed in a Web Forms page's class file, including both HTML and Web server controls.
In order to make sure user input contains only valid values, you can use one of the following validation controls:
 a. "RangeValidator": checks that a user's entry (value) is between specified lower and upper boundaries. You can check ranges within pairs of numbers, alphabetic characters, and dates.
 b. "RegularExpressionValidator": checks that the entry matches a pattern defined by a regular expression. This type of validation allows you to check for predictable sequences of characters, such as those in social security numbers, e-mail addresses, telephone numbers, postal codes, and so on.
Important note: validation controls do not block user input or change the flow of page processing; they only set an error state, and produce error messages. It is the programmer's responsibility to test the state of the controls in the code before performing further application-specific actions.
There are two ways to check for user input validity:
1. Testing for a general error state:
In your code, test the page's IsValid property. This property rolls up the values of the IsValid properties of all the validation controls on the page (using a logical AND). If one of the validation controls is set to invalid, the page's property will return false.
2. Testing for the error state of individual controls:
Loop through the page's Validators collection, which contains references to all the validation controls. You can then examine the IsValid property of each validation control.

PHP Fix Recommendations

** Filter User Input
Before passing any data to a SQL query, it should always be properly filtered with whitelisting techniques. This cannot be over-emphasized. Filtering user input will correct many injection flaws before they arrive at the database.
** Quote User Input
Regardless of data type, it is always a good idea to place single quotes around all user data if this is permitted by the database. MySQL allows this formatting technique.
** Escape the Data Values
If you're using MySQL 4.3.0 or newer, you should escape all strings with mysql_real_escape_string(). If you are using an older version of MySQL, you should use the mysql_escape_string() function. If you are not using MySQL, you might choose to use the specific escaping function for your particular database. If you are not aware of an escaping function, you might choose to utilize a more generic escaping function such as addslashes().
If you're using the PEAR DB database abstraction layer, you can use the DB::quote() method or use a query placeholder like ?, which automatically escapes the value that replaces the placeholder.

http://pear.php.net/package-info.php?package=DB
** Input Data Validation:
While data validations may be provided as a user convenience on the client-tier, data validation must always be performed on the server-tier. Client-side validations are inherently insecure because they can be easily bypassed, e.g. by disabling Javascript.
A good design usually requires the web application framework to provide server-side utility routines to validate the following:
[1] Required field
[2] Field data type (all HTTP request parameters are Strings by default)
[3] Field length
[4] Field range
[5] Field options
[6] Field pattern
[7] Cookie values
[8] HTTP Response
A good practice is to implement a function or functions that validates each application parameter. The following sections describe some example checking.
[1] Required field
Always check that the field is not null and its length is greater than zero, excluding leading and trailing white spaces.
Example of how to validate required fields:
```
  // PHP example to validate required fields
  function validateRequired($input) {

     ...
     $pass = false;
     if (strlen(trim($input))>0){
        $pass = true;
     }
     return $pass;
```

```
      ...
    }
   ...
   if (validateRequired($fieldName)) {
      // fieldName is valid, continue processing request
      ...
   }
```
[2] Field data type
In web applications, input parameters are poorly typed. For example, all HTTP request parameters or cookie values are of type String. The developer is responsible for verifying the input is of the correct data type.
[3] Field length
Always ensure that the input parameter (whether HTTP request parameter or cookie value) is bounded by a minimum length and/or a maximum length.
[4] Field range
Always ensure that the input parameter is within a range as defined by the functional requirements.
[5] Field options
Often, the web application presents the user with a set of options to choose from, e.g. using the SELECT HTML tag, but fails to perform server-side validation to ensure that the selected value is one of the allowed options. Remember that a malicious user can easily modify any option value. Always validate the selected user value against the allowed options as defined by the functional requirements.
[6] Field pattern
Always check that user input matches a pattern as defined by the functionality requirements. For example, if the userName field should only allow alpha-numeric characters, case insensitive, then use the following regular expression:
^[a-zA-Z0-9]+$
[7] Cookie value
The same validation rules (described above) apply to cookie values depending on the application requirements, e.g. validate a required value, validate length, etc.
[8] HTTP Response
[8-1] Filter user input
To guard the application against cross-site scripting, the developer should sanitize HTML by converting sensitive characters to their corresponding character entities. These are the HTML sensitive characters:
< > " ' % ;) (& +
PHP includes some automatic sanitization utility functions, such as htmlentities():
```
  $input = htmlentities($input, ENT_QUOTES, □UTF-8□);
```
In addition, in order to avoid UTF-7 variants of Cross-site Scripting, you should explicitly define the Content-Type header of the response, for example:
```
  <?php

    header('Content-Type: text/html; charset=UTF-8');

  ?>
```
[8-2] Secure the cookie
When storing sensitive data in a cookie and transporting it over SSL, make sure that you first set the secure flag of the cookie in the HTTP response. This will instruct the browser to only use that cookie over SSL connections.
You can use the following code example, for securing the cookie:
```
  <$php

    $value = "some_value";
```

```
$time = time()+3600;
$path = "/application/";
$domain = ".example.com";
$secure = 1;

setcookie("CookieName", $value, $time, $path, $domain, $secure, TRUE);
?>
```

In addition, we recommend that you use the HttpOnly flag. When the HttpOnly flag is set to TRUE the cookie will be made accessible only through the HTTP protocol. This means that the cookie won't be accessible by scripting languages, such as JavaScript. This setting can effectively help to reduce identity theft through XSS attacks (although it is not supported by all browsers).
The HttpOnly flag was Added in PHP 5.2.0.

Sun Java System Calendar Server Denial of Service

Infrastructure

WASC Threat Classification

Denial of Service

http://projects.webappsec.org/Denial-of-Service

CVE ID(s)

CVE-2009-1219

CWE ID(s)

20

Security Risks

It is possible to prevent the web application from serving other users (denial of service)

Possible Causes

Latest patches or hotfixes for 3rd. party products were not installed

Technical Description

Sun Java System Calendar Server is vulnerable to a Denial of Service attack through the "tzid" parameter, which allows an attacker to crash the server.
Sample Exploit:
https://[SERVER]3443/?tzid=[..]

General Fix Recommendations

Apply patches for Sun Java System Calendar Server 6.3.

Unencrypted Login Request

Application

WASC Threat Classification

Application Privacy Tests

CVE ID(s)

N/A

CWE ID(s)

523

Security Risks

It may be possible to steal user login information such as usernames and passwords that are sent unencrypted

Possible Causes

Sensitive input fields such as usernames, password and credit card numbers are passed unencrypted

Technical Description

During the application test, it was detected that an unencrypted login request was sent to the server. Since some of the input fields used in a login process (for example: usernames, passwords, e-mail addresses, social security number, etc.) are personal and sensitive, it is recommended that they will be sent to the server over an encrypted connection (e.g. SSL).
Any information sent to the server as clear text, may be stolen and used later for identity theft or user impersonation.
In addition, several privacy regulations state that sensitive information such as user credentials will always be sent encrypted to the web site.

General Fix Recommendations

1. Make sure that all login requests are sent encrypted to the server.
2. Make sure that sensitive information such as:
   - Username
   - Password
   - Social Security number
   - Credit Card number
   - Driver's License number
   - e-mail address
   - Phone number
   - Zip code
is always sent encrypted to the server.

Insecure HTTP Methods Enabled

Infrastructure

WASC Threat Classification

Content Spoofing

http://projects.webappsec.org/Content-Spoofing

CVE ID(s)

N/A

CWE ID(s)

N/A

Security Risks

It is possible to upload, modify or delete web pages, scripts and files on the web server

Possible Causes

The web server or application server are configured in an insecure way

Technical Description

It seems that the web server is configured to allow one (or more) of the following HTTP methods (verbs):
- DELETE
- SEARCH
- COPY
- MOVE
- PROPFIND
- PROPPATCH
- MKCOL
- LOCK
- UNLOCK
- PUT
These methods may indicate that WebDAV is enabled on the server, and may allow unauthorized users to exploit it.

General Fix Recommendations

If you do not need WebDAV enabled on your server, make sure that you either disable it, or disallow HTTP methods (verbs) that are unneeded.
